From a clinical point of view upper limb thromboembolism represents a vascular emergency so that the delay in treatment is highly likely to imply dramatic complications.

- 1st step - angiography
- 2nd step - recanalisation and thrombectomy
- 3rd step - angiography

For patients who has contraindications for vascular surgery and CDT or who prefers less invasive surgery, we offer alternative procedure - percutaneous mechanical thrombectomy with Casper CAS System (Microvention).

The percutaneous mechanical thrombectomy with Casper CAS System is less traumatic compared with traditional surgery, does not have absolute contraindications and can be used in patients with severe concomitant pathology.
